# **A rapidly convergent descent method for minimization**

R. Fletcher and M. J. D. Powell  
The computer journal, 1963.

# Preliminary: Newton's method

---

We are interested in finding the minimum of an unrestricted, twice-differentiable at all points, and convex function  $f$ :

$$\min_x f(x)$$

**Gradient descent:**

$$x_{t+1} = x_t - \eta \nabla f(x_t)$$

**Newton's method:**

$$x_{t+1} = x_t - G(x_t)^{-1} \nabla f(x_t),$$

where  $G$  is the second-order derivative.

## Preliminary: Newton's method (continued)

---

Taylor series second-order approximation of  $f$  at a local point:

$$f(x) \approx f(x_t) + \nabla f(x_t)(x - x_t) + \frac{1}{2}\nabla^2 f(x_t)(x - x_t)^2$$

The minimum of  $f(x)$  is found by setting its gradient to 0:

$$\begin{aligned}\nabla f(x) &= \nabla f(x_t) + \nabla^2 f(x_t)(x - x_t) \\ &= 0 \\ \Leftrightarrow x &= x_t - G(x_t)^{-1}\nabla f(x_t)\end{aligned}$$

This works because the second-order terms in the Taylor series expansion dominate near the minimum.

# Quasi-Newton method

---

Computing  $G(x_t)^{-1}$  is extremely expensive.

- Computing Hessian takes  $\mathcal{O}(n^2)$ .
- Matrix inverse takes  $\mathcal{O}(n^3)$ .

**Solution:** let us approximate  $G^{-1}(x_t)$  iteratively.

- Let us denote the approximation as  $H_t \approx G^{-1}(x_t)$ .
- $x_{t+1} = x_t - H_t \nabla f(x_t)$  for each  $t^{\text{th}}$  iteration
- Relevant method [Householder 1953] frequently fails to converge from a poor approximation to the minimum.

# Secant equation for approximating Hessian

---

Recall the **first**-order derivative:

$$\frac{d}{dx}f(x) = \lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x) - f(x)}{x + \Delta x - x}$$

Approximating the **second**-order derivative of  $G_t \approx \nabla^2 f(x_t)$ :

$$G_{t+1} \approx \frac{\nabla f(x_{t+1}) - \nabla f(x_t)}{x_{t+1} - x_t}$$

$$G_{t+1}(x_{t+1} - x_t) \approx \nabla f(x_{t+1}) - \nabla f(x_t)$$

By setting  $H_{t+1} := G_{t+1}^{-1}$ ,  $s := x_{t+1} - x_t$  and  $y := \nabla f(x_{t+1}) - \nabla f(x_t)$ :

$$H_{t+1}y = s$$

# Symmetric rank-1 update (Davidon) <sup>1</sup>

---

Assumption:  $H_{t+1}$  from  $H_t$  follows rank-1 update such as:

$$H_{t+1} = H_t + a u u^\top,$$

where  $a$  is a scalar value and  $u$  is an arbitrary vector.

Combining the secant equation  $H_{t+1}y = s$  and setting  $u = \alpha(H_t y - s)$  leads to:

$$\begin{aligned} H_t y + a(\alpha(H_t y - s))(\alpha(H_t y - s))^\top y &= s. \\ \Rightarrow H_{t+1} &= H_t + \frac{(s - H_t y)(s - H_t y)^\top}{(s - H_t y)^\top y} \end{aligned}$$

This update has following limitations:

- $(s - H_t y)^\top y \approx 0$  may fail to update.
- $H_t$  is not guaranteed to be positive semi-definite.

---

<sup>1</sup>Derivation taken from a lecture note, CMU [Javier Pěna 2016]

# Symmetric rank-2 update (Davidon-Fletcher-Powell)

---

Assumption:  $H_{t+1}$  from  $H_t$  follows rank-2 update such as:

$$\begin{aligned}H_{t+1} &= H_t + auu^\top + bv v^\top \\H_{t+1}y &= H_t y + auu^\top y + bv v^\top y = s \\ \Leftrightarrow s - H_t y &= au^\top y u + bv^\top y v\end{aligned}$$

where  $a$  and  $b$  are scalar values and  $u$  and  $v$  are arbitrary vectors.

By setting  $u := s$  and  $v := H_t y$ :

$$H_{t+1} = H_t - \frac{H_t y y^\top H_t}{y^\top H_t y} + \frac{ss^\top}{y^\top s}$$

# Stability

---

$H_t$  is positive definite  $\rightarrow$  the convergence is stable.

Let  $z$  be an arbitrary vector.

$$\begin{aligned}H_{t+1} &= H_t - \frac{H_t y y^\top H_t}{y^\top H_t y} + \frac{s s^\top}{y^\top s} \\ \Rightarrow z^\top H_{t+1} z &= z^\top H_t z - \frac{z^\top H_t y y^\top H_t z}{y^\top H_t y} + \frac{z^\top s s^\top z}{y^\top s} \\ &= \frac{p^\top p q^\top q - (p^\top q)^2}{q^\top q} + \frac{(s^\top z)^2}{y^\top s} \quad \text{where } p = H_t^{1/2} z \text{ and } q = H_t^{1/2} y \\ &\geq \frac{(s^\top z)^2}{y^\top s} \\ &> 0\end{aligned}$$

on account of Schwartz's inequality.

# Experiment

---

Function (1):

- $f(x_1, x_2) = 100(x_2 - x_1^2)^2 + (1 - x_1)^2$ .
- This function is difficult to minimize on account of its having a steep sided valley following  $x_1^2 = x_2$ .

Function (2):

- $f(x_1, x_2, x_3) = 100[x_3 - 10\theta(x_1, x_2)]^2 + [r(x_1, x_2) - 1]^2 + x_3^2$ .
- $2\pi\theta(x_1, x_2) = \begin{cases} \arctan(x_2/x_1) & \text{if } x_1 > 0, \\ \pi + \arctan(x_2/x_1) & \text{otherwise.} \end{cases}$
- $r(x_1, x_2) = (x_1^2 + x_2^2)^{1/2}$
- This function has a helical valley in the  $x_3$  direction with pitch 10 and radius 1.

# Experiment: function (1)

- $f(x_1, x_2) = 100(x_2 - x_1^2)^2 + (1 - x_1)^2$ .
- $\min f(x_1, x_2) = (1, 1)$

# Conclusion

---

Takeaway:

- This paper presents a Quasi-Newton method that iteratively approximates the inverse of Hessian using rank-2 update.

What I learned from reading this paper:

- Valuable experience of reading a classic paper
- Not easy to fully understand due to classical notations and unkind writing.
- Studied background of the second-order gradient methods.

# Midterm progress

Analysis on second-order optimization method:  
Newton's and Quasi-Newton method

# The goal of the project

---

Understanding & in-depth analysis on second-order gradient methods.

Three representative second-order gradient methods that we chose are:

- Vanilla Newton's method
- A Quasi-Newton method (DFP [Fletcher and Powell 1963])
- A recent method (AdaHessian [Yao et al. 2021])

We will implement these methods and analyze them in two-variate convex functions.

# Progress

---

- Studied the background of second-order methods.
- Implemented code skeleton

# Plan

---

- ~~Apr. 14th - Apr. 30th : Survey & study~~
- May. 1st - May. 19th : Implement Newton's, Quasi-Newton, AdaHessian method
- May. 20th - May. 26th : Implement evaluation pipeline.
- May. 26th - Jun. 1st : Analysis
- Jun. 2nd - Jun. 4th : Final report & prepare for presentation

- Any questions?

## Stability (continued)

---

$H_t$  is positive definite  $\rightarrow$  the convergence is stable.

Let  $z$  be an arbitrary vector.

$$\begin{aligned} H_{t+1} &= H_t - \frac{H_t y y^\top H_t}{y^\top H_t y} + \frac{s s^\top}{y^\top s} \\ &\geq \frac{(s^\top z)^2}{y^\top s} \end{aligned}$$

$$\begin{aligned} y^\top s &= (\nabla f(x_{t+1}) - \nabla f(x_t))^\top (x_{t+1} - x_t) \\ &= -\nabla f(x_t)^\top (x_{t+1} - x_t) \\ &= \nabla f(x_t)^\top H_t \nabla f(x_t) \\ &> 0 \end{aligned}$$
